(54) Title: TEMPORARY SEAL AND METHOD FOR FACILITATING ANASTOMOSIS

(57) Abstract: Forming a proximal anastomosis on an aortic wall includes method and instrumentation and apparatus for forming an aortic puncture and inserting a fluid-impervious sealing element with a lateral flange and central stem into the vessel through the puncture. An anastomosis of a graft vessel over the puncture is partially completed with the central stem of the sealing element protruding through the partial anastomosis. A removal instrument attaches to the central stem and retrieves the sealing element that disassembles in helical disassociation of the flange and stem into a continuous strand that is withdrawn from the partial anastomosis prior to completion of the procedure.

WO 03/057062 A2

## TEMPORARY SEAL AND METHOD

### FOR FACILITATING ANASTOMOSIS

#### Field of the Invention:

[0001] This invention relates to coronary bypass grafting surgery and more particularly to instruments and method to facilitate performing an aortotomy and proximal anastomosis, for example, associated with coronary artery bypass grafting surgery.

#### Background of the Invention:

10 [0002] Contemporary coronary artery bypass grafting surgery is performed on a beating heart to obviate complications commonly associated with prior surgical practices of transitioning a patient onto and off of a heart-lung machine that maintained circulation while the heart was in quiescent condition during construction of a coronary arterial bypass. However, performing an aortotomy and a proximal anastomosis on the aorta that is perfused with blood under pressure contribute to substantial losses of blood in the absence of temporary measures taken to curtail blood flow through the aortic hole. Side-bite and surface-oriented clamping mechanisms have been used to diminish loss of blood during the surgical procedures of punching the aortic hole and anastomosing the graft vessel, 15 but such temporary occlusions damage the endothelium and dislodge emboli that may migrate through the circulatory system. Alternative schemes for performing an aortotomy and limiting loss of blood during the period of anastomosing a bypass graft include introducing a plug or seal at the site of the aortotomy, but such schemes commonly inhibit convenient and rapid completion of the graft anastomosis, and present other complications to be resolved following the grafting procedure. 25

#### Summary of the Invention:

[0003] In accordance with the method and instrumentation of the present invention, an aorto-coronary bypass graft is performed using an aortic punch including a corkscrew instrument and a hemostatic sheath that selectively delivers and positions a seal within the punched aortic hole for retention against the aortic wall under tension established by an external structure. The suture anastomosis is performed with the hemostatic seal in place and with a central stem of the seal residing near the location of the last placed stitch. A tubular removal instrument is positioned about the protruding stem to remove the seal as a tear-away strip that is pulled through the tubular removal instrument.

10

Brief Description of the Drawings:

Detailed Description of the Invention:

[0023] Referring now to Figures 1, 2 and 3, there are shown pictorial views of the aortic punch 9 configured for penetrating the aorta 17 of a patient in preparation for a proximal anastomosis of a bypass vessel to the aorta of the patient. Specifically, an outer hemostatic sheath 11 is coaxially disposed over the lower elongated segment 13 of the aortic punch which supports a corkscrew-type auger 15, as shown in Figures 14 and 15. The punch and auger 15 are rotated into a wall of the aorta 17 and the plunger 19 can then be depressed to penetrate the sharpened edge of the lower elongated segment 13 through the aorta wall. The punched-out segment of aorta wall remains captivated on the cork screw 15, and the hemostatic sheath 11 is positioned within the punched hole through the aorta wall. The plunger mechanism 19 and attached elongated lower segment is removed from the hemostatic sheath 11 that remains in position through the aorta wall, as shown in Figure 3. A fluid-tight seal is included within the hemostatic sheath 11 to inhibit outflow of blood under pressure from the aorta 17 in which it is positioned.

[0024] Referring now to the pictorial illustration of Figure 4, there is shown a seal-insertion instrument 21 that includes a sheath 23 of outer diameter sized to slide within the hemostatic sheath 11, and a plunger 25 that is disposed to slide axially within the sheath 23 for selectively ejecting the hemostatic seal structure 27 from its confinement within the sheath 23. The hemostatic seal structure 27, as later described herein with reference to Figure 16, includes resilient members that are confined within the sheath 23 in preparation for positioning and expansion into sealing engagement with the aorta wall, as later described herein.

[0025] Referring now to the pictorial illustrations of Figures 5 and 6, the seal-insertion instrument 21 is inserted into the hemostatic sheath 11 through the fluid-tight seal therein, and the plunger 25 is depressed to eject a portion of the hemostatic seal structure 27, within the aorta 17. The plunger 25 includes an axial lumen therethrough to pass a length of line 28 that is attached to the hemostatic

seal structure 27. The proximal end of plunger 25 may also include a hemostatic seal 100 through which the length of line 28 passes.

[0026] As illustrated in Figures 6, 7, 16 and 17, a convex or mushroom-shaped sealing element 29 of the hemostatic seal structure 27 is deployed and manually restrained within the aorta 17 covering the punched aortic hole as the hemostatic sheath 11 and the seal-insertion instrument 21 are removed together from the aorta 17. The hemostatic seal structure 27 is thereby liberated from confinement within the seal-insertion instrument 21 to expand into sealing engagement with the aorta wall inside the punched aortic hole.

10 [0027] Referring now to Figure 16, the hemostatic seal structure 27 includes the convex or mushroom-shaped sealing element 29, and this sealing element 29 includes an integral central stem 30 that is attached via a suture tether 32 to a resilient frame 34 which tensions the suture tether 32. The resilient frame 34 is attached to the length of line 28 that passes through an axial lumen through the  
15 plunger 25 as the entire structure is packed in confined configuration within the hollow sheath 23 of the seal-insertion instrument 21. When ejected from the hemostatic sheath 23 upon depression of the plunger 25, the resilient frame 34 expands to tension the suture tether 32. Manual positioning by the surgeon's finger, as shown in Figure 7, promotes proper sealing of the hole in the aorta as  
20 the resilient frame 34 expands to tension the suture tether 32. As thus positioned in this configuration, the resilient frame 34 maintains tension on the suture tether 32 that, in turn, supports the sealing element 29 from outside the aorta to provide outwardly-directed resilient biasing force on the sealing element 29. This resilient force establishes firm sealing engagement of the sealing element 29 against the  
25 inside wall of the aorta. In addition, the suture tether 32 greatly facilitates removal of the resilient frame 34, as later described herein, upon simply cutting one or both ends of the suture tether 32 away from the resilient frame 34 for removal from the sealing element 29. In one embodiment the suture-tether 32 may pass through the convex segment of the sealing element 29 to the concave

side thereof on both sides of the central stem 30. In another embodiment, the suture tether 32 may be tied to the central stem 30 closely adjacent the concave surface of the sealing element 29.

[0028] The sealing element 29 is formed in accordance with one embodiment of the present invention, as illustrated in Figure 17. Specifically, a hollow tube 33 of flexible material such as polyvinyl chloride, PEBAX, or other polymer material may be extruded about a looped suture 35 or wire or other tensile member for improved tensile strength. Alternatively, a solid, flexible rod of similar material having sufficient tensile strength may be used. The hollow tube (or solid rod) 33 may be helically or spirally wound into the configuration of the mushroom-shaped sealing member 29, with the central stem 30 integrally formed thereon. The adjacent convolutes of the spirally-wound tube 33 with suture 35 or other tensile member disposed therein (or solid rod) may be lightly adhered together through the application of heat and pressure to a thermoplastic material, or through other suitable adhesive attachments to form the substantially fluid-impervious sealing element 29 that is flexible and resilient for confined packing within the hollow sheath 23 of the seal-insertion instrument 21. Light adhesion between adjacent convolutes of the spirally-wound tube 33 with a suture therein (or solid rod) promotes disassembly of the sealing element 29 as by tearing along the boundary between adjacent convolutes under tension applied to the central stem 30, as later described herein. It should be noted that the central stem 30 is an integral and continuous portion of the spiral convolutes (or other meandering pattern) that extend continuously from the central stem portion 30 to the outer perimeter of the mushroom-shaped portion of the sealing element 29. This assures substantially uniform high tensile strength of the hollow tube 33 with suture 35 disposed therein (or solid rod) over the entire continuous length of the tube 33 to assure complete removal from the aorta in the manner as later described herein. In one embodiment, the sealing element 29 may be formed by winding the hollow tube 33 (or solid rod) around a mandrel that includes separable flanges which are

axially spaced apart by about the diameter dimension of the tube 33 (or solid rod), and that includes a central hollow support to house the portion that forms the central stem 30. Heat and pressure applied between such flanges causes thermoplastic flow and adhesion between adjacent convolutes in the mushroom-shaped portion and to the stem 30 in the central portion of the fluid-impervious sealing element 29 thus formed. Alternatively, bioinert adhesive may be applied to the convolutes and central stem 30 to retain the shape of the fluid-impervious sealing element 29 thus formed.

[0029] Referring now to the pictorial illustration of Figure 8, the sealing element 29 is shown disposed in sealing position inside the punched aortic hole with the integral stem 30 protruding through the hole, and with suture loop 35 protruding from the proximal end of the stem 30. It should be noted that the resilient frame 34 and the suture tether 32 are positioned on the outer wall of the aorta to exert an outwardly-directed force on the sealing element 29 to retain it in sealing engagement with the inner aortic wall, and to prevent inadvertent expulsion of the sealing element 29 from the hole or loss of the sealing element 29 into the aorta. The sealing element 29 is thus maintained in sealing position over the hole in the aorta during formation of the proximal anastomosis by suturing the graft vessel 37 onto the aorta 17, as shown in Figures 9-11. The stem 30 is flexible and can be gently pushed out of the way of sutures that are stitched about the hole in the aorta and into the proximal end of the graft vessel 37. In this way, the stem 30 is left protruding through the anastomosis at a position thereon near the last stitch (or between any adjacent stitches).

[0030] Referring now to Figures 10-12 and 18, a seal-removal instrument 41 includes an outer tube 43 with an inner core 45 that is slidable within the outer tube 43 and that carries a hook 47 at its distal end. The assembly of inner core 45 disposed within the outer tube 43 is positioned over the stem 30 of the sealing element 29 with the hook 47 engaged in the suture loop 35. The outer tube 43 is positioned onto the stem 30 down to the root of its attachment to the mushroom-

shaped spiral-wound sealing element 29, and the inner core 45 is then withdrawn from the outer tube 43. These motions cause the spirally-wound convolutes of the sealing element 29 to tear and otherwise disassemble for convenient removal as a continuous strand 29', as shown in Figure 12, of the material from which the spirally-wound sealing element 29 was formed. Thereafter, the outer tube 43 may be withdrawn and the sutures tied off near where outer tube 43 was positioned to complete the proximal anastomosis, as shown in Figure 13.

[0031] Alternatively, the central stem 30 may be formed as an integral part of the mushroom-shaped portion of the sealing element 29 with sufficient length to extend through the outer tube 43 adequately to permit finger gripping of the stem 30 for manual tensioning and removal of the continuous strand 29' through the outer tube 43 without the need for the hooked inner core 45 and associated suture loop 35.

[0032] Referring now to the flow chart of Figure 19, an embodiment of the surgical procedure performed according to the present invention includes forming an aperture 51 in the aorta wall, as illustrated in Figures 1 and 2. The hemostatic seal structure in confined configuration within the hemostatic sheath is then introduced 53 into the aorta through the hole in the wall thereof. The sealing element resiliently expands 55 inside the aorta to form a fluid-tight seal over the hole in the wall, and is supported 57 on a tensioned tether from the outside of the aorta. A central stem portion of the sealing element is sufficiently flexible to be pushed away from the locations on the aorta at which suture stitches are inserted during substantial completion 59 of anastomosing the graft vessel to the aorta over the hole in the wall thereof. The central stem portion of the sealing element thus protrudes through the anastomosis between adjacent stitches and is accessible to facilitate removal of the sealing element disposed within the aorta beneath the anastomosis. The sealing element is removed through a tube that is positioned over the central stem portion by applying tensile force to the central stem portion relative to the tube. This disassembles or unravels the sealing element into a

single strand 61 that is removed through the tube 63, as shown in Figure 12. The ends of the suture adjacent to the location on the anastomosis through which the strand was removed may then be tied off to complete the anastomosis 65.

[0033] Referring now to Figure 20, there is shown a pictorial illustration of a kit of instruments and components suitable for performing the surgical procedure according to the present invention, as previously described herein. Specifically, at least the seal-insertion instrument 21 and seal removal tube 43 are packaged within a sealed enclosure 67 that preserves a sterile environment and facilitates convenient shipping and handling of these components without contamination or damage. Additionally, a hemostatic sheath 11 may be included within the enclosure 67 for use with a punch (separately available to a surgeon) in the manner as previously described herein with reference to Figures 1 and 2.

[0034] Therefore, the surgical devices and procedures for forming a temporary aortic seal during proximal anastomosis of a graft vessel to the aorta greatly facilitates removal of the temporary seal with negligible risk of any residual debris being created thereby to circulate in blood flowing in the aorta or in the graft vessel. Additionally, the sealing element of the present invention promotes self sealing of an aortotomy during formation of the vessel graft, aided by a resilient frame that is disposed outside the aorta to support the sealing element during formation of the anastomosis. The resilient frame is easily removed at a convenient stage in the procedure. The sealing element thus positioned to seal off the aortotomy during formation of the anastomosis can be conveniently disassembled into a continuous strand that is pulled from the surgical site with minimal additional trauma or complication of the surgical procedure.

Claims

1. A method for forming a proximal anastomosis of a graft vessel on a fluid-carrying vessel in a patient's body, the method comprising:
- 5 forming an aperture in a wall of the vessel;
- introducing through the aperture and into the vessel in confined configuration a resilient, flexible sealing element having a central stem and having a continuous disassociation region formed thereon to extend from the central stem;
- 10 expanding the sealing element to peripheral dimensions greater than the dimension of the aperture;
- retaining the sealing element in position covering the aperture in sealing engagement within the vessel;
- substantially completing anastomosing the graft vessel on the fluid-carrying vessel over the aperture, retaining an incomplete segment overlapping the central
- 15 stem for removal of the sealing element;
- disassembling the expanded sealing element along the disassociation region extending from the central stem for removal thereof as a continuous strand through the incomplete segment; and
- 20 completing the anastomosis of the graft vessel on the fluid-carrying vessel including along the incomplete segment.
2. The method according to claim 1 in which forming an aperture includes augering into a wall of the fluid-carrying vessel in relation to a cutting edge for cutting tissue in the vessel wall to form the aperture and retaining the tissue cut therefrom.
- 25 3. The method according to claim 1 in which a resilient retainer is positioned on an outer wall of the vessel near the aperture for supporting a filament thereon in tension that is attached to the sealing element through the aperture to retain the sealing element in the sealing engagement with an inner wall of the fluid-carrying vessel.

4. The method according to claim 1 in which substantially completing anastomosing the graft vessel includes forming suture attachment thereof to the fluid-carrying vessel about the perimeter of the aperture, with the central stem of the sealing element extending through the anastomosis near the last suture

5 attachment;

disassembling the sealing element along the disassociation region thereof for withdrawal as a single continuous strand through the incomplete segment of the anastomosis; and

completing the anastomosis following removal of the sealing element.

10 5. The method according to claim 4 in which disassembling the sealing element includes introducing an elongated tube over the central stem and through the incomplete segment of the anastomosis; and

exerting tensile force on the central stem relative to the elongated tube to pull therethrough the central and subsequent portions of the sealing element as  
15 disassembled into a single continuous strand along the disassociation region.

6. The method according to claim 1 in which the disassociation region extends along a spiral path between the central stem and perimeter of the sealing element.

7. A method for forming a sealing element for insertion and removal  
20 with respect to a fluid-carrying vessel of a patient, the method comprising:

forming fluid-impervious flange extending radially from a central region to a substantially circular periphery; and including

forming a continuous disassociation region along a meandering path from the central region to the circular periphery.

25 8. The method according to claim 7 including

forming a central stem on the flange and integral therewith along the continuous dissociation region.

9. The method according to claim 7 including

forming an attachment structure near a proximal end of the stem for exerting tensile force thereon.

10. The method according to claim 7 in which the flange is formed as a continuously-wound spiral of thermoplastic material having contiguous lateral  
5 edges along adjacent convolutes; and

selectively heating and pressing together the lateral edges of contiguous convolutes to lightly adhere the convolutes to form the fluid-impervious flange of the sealing element.

11. The method according to claim 7 in which the flange is formed with a  
10 continuous disassociation pattern of reduced thickness of the flange from a central region thereof to the periphery thereof for promoting disassembly of the flange along the disassociation pattern into a continuous strand from the central region to the periphery of the flange in response to force applied at the central region in relation to the flange.

15 12. A method of forming a temporary fluid-impervious sealing element comprising:

configuring a strand along a path and including an axial stem and a substantially lateral flange, with the path continuously meandering between the stem and an outer periphery of the flange; and

20 adhering contiguous adjacent segments of the strand in the stem and flange to form the fluid-impervious sealing element.

13. The method according to claim 12 in which the path substantially spirals between the stem and periphery of the flange with adjacent convolutes of the strand disposed in substantially contiguous array along the path.

25 14. The method according to claim 13 in which the strand includes thermoplastic material; and

adhering includes applying heat and pressure at least to the flange to flow the material into fluid impervious attachments of contiguous adjacent convolutes of the strand.

15. A method for establishing a temporary fluid-tight seal within an aperture in a wall of a fluid-carrying vessel in the body of a patient, the method comprising:

introducing through the aperture a sealing element having a flange of  
5 substantially circular periphery and stem substantially normal to the flange in a central region thereof; and

exerting a supporting force through the aperture on one of the stem and flange for retaining fluid-sealing engagement of the circular periphery of the flange against an inner wall of the vessel covering the aperture.

10 16. The method according to claim 15 in which the flange of the sealing element includes substantially convex shape intruding into the vessel with the circular periphery thereof disposed about the aperture.

17. The method according to claim 15 in which a resilient member is disposed on an outer wall of the vessel and in which a tether is disposed in tension  
15 on the resilient member and extends through the aperture for attachment with the one of the stem and flange to exert the supporting force thereon.

18. A temporary sealing element for forming a fluid-tight seal on the inner wall of a fluid conduit within a patient's body, the temporary sealing element comprising:

20 a fluid impervious flange having an outer stem centrally formed thereon, the flange including a continuous region of diminished shear strength extending from the stem along a continuous path to the periphery for selectively reconfiguring the flange in response to tension applied to the stem to dissemble the flange along the continuous region into a continuous strand.

25 19. The temporary sealing element according to claim 18 including a length of flexible, resilient material integrally forming the stem, and being helically wound to form successive convolutes outwardly from the stem to the periphery, with each convolute adhering to adjacent convolutes along lateral edges thereof to form the continuous region in the substantially fluid-impervious flange.

20. The temporary sealing element according to claim 19 in which the length of material includes a length of bioinert thermoplastic material forming the stem and flange and including thermoplastic adhesion between lateral edges of adjacent convolutes of the helically-wound length of material.

5 21. The temporary sealing element according to claim 19 in which the thermoplastic material is polyvinyl chloride.

22. The temporary sealing element according to claim 19 including an attachment structure at an end of the stem remote from the flange for selective engagement therewith to exert tensile force thereon.

10 23. The temporary sealing element according to claim 19 including a support structure attached to one of the stem and flange and including a resilient member disposed to expand from a confined configuration of smaller lateral dimension than the periphery of the flange to an expanded configuration of larger lateral dimension than the periphery of the flange.

15 24. The temporary sealing element according to claim 23 in which the resilient member extends laterally and includes a pair of mating ends disposed to traverse the periphery of the flange; and

a strand attached to the mating ends and to one of the stem and flange for supporting the stem and flange intermediate the mating ends of the resilient  
20 member.

25. The temporary sealing element according to claim 24 in which the resilient member includes a pair of arms extending to and including the mating ends and resiliently biased for outward extension of the mating ends.

26. The temporary sealing element according to claim 18 in which the  
25 flange is formed of flexible resilient material and includes a generally circular periphery and the stem integrally formed therewith; and in which the region of diminished shear strength extends from the stem along a substantially helical path to the periphery.

27. A seal removal instrument for the temporary sealing element of claim 22 including an elongated hollow tube having a lumen therethrough between distal and proximal ends dimensioned to pass the stem and attachment structure therethrough;

5 an inner core slidably disposed within the tube and including an attachment structure at a distal end thereof to mate with the attachment structure at the end of the stem for exerting tensile force thereon;

said tube being positionable about the stem with the distal end of the tube disposed adjacent the flange and with the attachment structures of the inner core and stem engaged to exert tensile force on the inner core relative to the tube for  
10 extracting the stem and flange through the outer tube as the continuous strand.

28. The seal removal instrument of claim 27 in which the attachment structure on the stem includes a loop, and the attachment structure on the inner core includes a hook for engaging the loop.

15 29. A punch for forming an aperture in the wall of the fluid-carrying vessel in a patient's body, the punch comprising:

an elongated hemostatic sheath including a lumen therethrough between distal and proximal ends thereof;

a plunger element slidably and rotatably disposed within the lumen through  
20 the hemostatic sheath and carrying a tissue-penetrating member for selective axial extension thereof beyond the distal end of the hemostatic sheath to penetrate the wall of a fluid-carrying vessel.

30. A punch according to claim 29 in which the tissue-penetrating member includes a corkscrew-style tissue penetrator and includes a substantially  
25 circular cutting edge in close proximity thereto mounted for relative rotational motion therebetween.

31. A punch accordingly to claim 29 including a valve disposed in the hemostatic sheath for inhibiting outflow of fluid therethrough.

32. A punch according to claim 30 in which the distal end of the hemostatic sheath forms the cutting edge in close proximity to the tissue penetrator.

33. A kit of surgical components for anastomosing a graft vessel on a fluid-carrying vessel, comprising:

a punch for forming an aperture in a fluid-carrying vessel;

a sealing element including a continuous strand of material extending along a path forming an axial stem and a substantially lateral flange to a perimeter thereof of dimension greater than an aperture formable by the punch; and

an insertion instrument incorporating the sealing element in configuration for positioning the sealing element within an aperture formable by the punch.

34. The kit according to claim 33 including an extraction instrument having a lumen extending therethrough of sufficient dimension between proximal and distal ends thereof for passing the strand of material therethrough.

35. The kit according to claim 33 including a resilient frame disposed about the sealing element and including a flexible tether that is tensioned by the frame and that engages the sealing element in a combined structure of sealing element supported by the tether on the resilient frame.

36. The kit according to claim 35 in which the insertion instrument includes an elongated hollow tube having proximal and distal ends, with the combined structure confined within the hollow tube near the distal end thereof in compressed configuration for selective deployment therefrom to a configuration that tensions the tether for supporting the sealing element on the resilient frame.

37. The kit according to claim 33 including an envelope surrounding the punch and sealing element and insertion instrument for maintaining a sterile environment thereabout.
